

dnsflowd

Live DNS Telemetry & Lightweight Blocking

A minimal, end-to-end pipeline for home and edge networks: **capture** → **transport** → **store** → **display** → **act**. Built on OpenWrt, Python, SQLite, and Flask — designed to be simple, teachable, and immediately useful.

User Interfaces

Web UI

The screenshot displays the DNSFlowd Web UI in a browser window. The interface is dark-themed and provides a comprehensive overview of DNS traffic. At the top, it shows the session ID 'ACT_7754_X', uptime of 00:00:12, and server location 'localhost'. Key statistics include 283 total events, 3 queries per minute, and 3 unique domains. A 'LIVE TRAFFIC STREAM' table lists individual queries and answers with columns for time, type, source IP, domain, and destination IP. On the right, a 'TOP TALKERS' table ranks domains by query volume, and a 'BLOCKED DOMAINS' section allows for managing a list of blocked domains. The bottom status bar indicates the system is ready and running on port 8080.

TIME	TYPE	SOURCE IP	DOMAIN	DST IP
19:49:48	ANSWER	1.1.1.1	142.250.86.46	192.168.1.10

CLI

The screenshot shows the DNSFlowd CLI interface in a terminal window. It displays the command to activate the virtual environment and start the server. The output shows the 'dnsflowd' logo, the dashboard URL (http://0.0.0.0:5000), the listener address (0.0.0.0:9999), and a message indicating that the Flask app 'web_ui' is serving on port 9999. The terminal also shows the network status and debug mode settings.

```
~: python3 — Konsole

New Tab Split View

blastille@blastille:~$ source ~/dnsflowd/.venv/bin/activate
(.venv) blastille@blastille:~$ python3 /home/blastille/dnsflowd/server/main.py
[Database] Setup complete.

dnsflowd

Dashboard -> http://0.0.0.0:5000
Listener -> 0.0.0.0:9999

[Network] Waiting for router connection on port 9999...
* Serving Flask app 'web_ui'
* Debug mode: off
```

Why DNS Telemetry?

DNS is the phone book of the internet. Every device consults it before connecting anywhere. Watching that traffic in real time gives you visibility into what your devices are doing, without deep packet inspection or heavyweight tooling.

Visibility

Monitor DNS queries per device in real time — see which hosts are talking to which domains.

Security

Centralize blocking for ads, trackers, and malware at the network edge — no per-device config needed.

Teachable

Demonstrate streaming ingestion, queuing, persistence, and a live web UI with minimal, readable code.

High-Level Architecture

Six small, decoupled components form the full pipeline. The router produces newline-delimited JSON; the server ingests, persists, and pushes live events to the dashboard. The blocker closes the loop by writing dnsmasq rules back to the router.

Algorithms Used in dnsflowd

Three core algorithms power the system:

Hashmaps (Dictionaries) — $O(1)$ average-time counting

Used in `server/analytics.py` to count how often each source IP appears in recent queries. Fast lookups and updates enable real-time frequency analysis.

```
# server/analytics.py
frequency_map = {}
for query in data:
    src = query.get("src_ip")
    if src in frequency_map:
        frequency_map[src] += 1
    else:
        frequency_map[src] = 1
```

Trees & Indexing — $O(\log n)$ search

SQLite indexes in `server/database.py` speed up searches on `detail`, `src_ip`, and blocked domains. Multi-column indexes enable efficient range queries and joins.

```
# server/database.py
cur.execute("CREATE INDEX IF NOT
EXISTS idx_detail_src ON dns_traffic
(detail, src_ip)")
cur.execute("CREATE INDEX IF NOT
EXISTS idx_blocked_domain ON
blocked_domains (domain)")
```

Sorting — $O(n \log n)$ ranking

Sorts the frequency map to rank the most active clients by request count and order recent records for dashboard display.

```
frequency_list =
list(frequency_map.items())
frequency_list.sort(key=lambda item:
item[1], reverse=True)
top_talkers = frequency_list[:10]
```

Why it matters: Hashmaps give us instant counting, indexes let us query millions of DNS events without full table scans, and sorting surfaces the most interesting data for the UI.

Router Capture Script

ROUTER-SCRIPT.SH

A single shell script on OpenWrt captures DNS packets with `tcpdump`, parses them with `awk` into JSON, and streams lines to the server via `netcat`. No extra packages beyond what OpenWrt provides by default.

What It Does

- Listens on `br-lan` for UDP port 53
- Parses queries and answers
- Outputs newline-delimited JSON
- Streams via `nc` to `SERVER_IP:9999`

```
#!/bin/sh
SERVER_IP="YOUR_SERVER_IP"
PORT="9999"

tcpdump -i br-lan -nn -l ip and udp port 53 |
awk -v ip="$SERVER_IP" -v port="$PORT" '
/A\?/ {
    dom = $8; sub(/\.$/, "", dom)
    printf "{\"type\":\"QUERY\",\"src\":\"%s\",\"domain\":\"%s\"}\n",
$3, dom
}
/A / {
    match($0, /A .*/)
    ans = substr($0, RSTART+2, RLENGTH-2)
    printf "{\"type\":\"ANSWER\",\"src\":\"%s\",\"data\":\"%s\"}\n",
$3, ans
}' | nc $SERVER_IP $PORT
```

Server Listener & Database

SERVER/MAIN.PY

SERVER/DATABASE.PY

The server accepts raw TCP connections, accumulates bytes, splits on newline, and safely parses each JSON line. Valid events are inserted into SQLite and — for queries — enqueued for the live dashboard. A separate thread starts the Flask UI on port 5000.

Listener Loop

```
def handle_client(sock, addr):
    buffer = ""
    while True:
        chunk = sock.recv(4096).decode()
        if not chunk: break
        buffer += chunk
        while "\n" in buffer:
            line, buffer = buffer.split("\n", 1)
            data = json.loads(line)
            database.insert_data(data)
            bridge.live_traffic_queue.put({...})
```

SQLite Schema

```
CREATE TABLE dns_traffic (
    id INTEGER PRIMARY KEY,
    timestamp DATETIME DEFAULT CURRENT_TIMESTAMP,
    log_type TEXT,
    src_ip TEXT,
    dst_ip TEXT,
    detail TEXT
);
CREATE TABLE blocked_domains (
    id INTEGER PRIMARY KEY,
    domain TEXT UNIQUE
);
CREATE INDEX idx_detail_src
ON dns_traffic(detail, src_ip);
```

Live Stream via Server-Sent Events

SERVER/BRIDGE.PY

SERVER/WEB_UI.PY

The `Queue` in `bridge.py` decouples ingestion from the UI thread — zero CPU polling, near-zero latency. Flask exposes `/stream` as an SSE endpoint; the browser reconnects automatically. A keepalive ping every 15 seconds prevents the browser from dropping the connection during quiet periods.

bridge.py — Queue

```
from queue import Queue
live_traffic_queue = Queue()
```

web_ui.py — SSE Generator

```
def _event_stream():
    while True:
        try:
            item = bridge.live_traffic_queue.get(
                timeout=15)
            yield f"data: {json.dumps(item)}\n\n"
        except Exception:
            yield ": ping\n\n" # keepalive
```

Web API & Blocklist Endpoints

SERVER/WEB_UI.PY

The Flask app serves the dashboard UI and a small REST API for blocklist management. The UI calls these endpoints to add or remove domains; responses indicate success, duplicates (409), or not-found (404).

GET /api/blocklist

Returns all currently blocked domains as a JSON array. Used by the dashboard to populate the blocklist table on load.

POST /api/blocklist

Accepts `{"domain": "example.com"}`. Validates, normalizes to lowercase, checks for duplicates, and inserts via `database.add_to_blocklist()`. Returns 409 if already blocked.

DELETE /api/blocklist

Removes a domain from the blocklist. Returns 404 if the domain was not found. The blocker will sync the updated list to the router on the next call.

Pushing Blocklist to the Router

SERVER/BLOCKER.PY

When the blocklist changes, `blocker.py` composes `dnsmasq` address rules and writes them to the router via SSH. A reload applies changes without dropping existing connections. The private key must be configured for passwordless SSH access.

dnsmasq Rule Format

Each blocked domain becomes a single line:

```
address=/ads.doubleclick.net/  
address=/tracker.example.com/
```

dnsmasq returns `0.0.0.0` for any matching query — effectively a sinkhole.

SSH Sync Logic

```
def sync_blocklist_to_router(force=False):  
    domains = database.get_all_blocked_domains()  
    payload = "".join(  
        f"address={d}/\n" for d in domains)  
  
    # Write config file  
    subprocess.run(  
        base_ssh + [f"cat > {BLOCKLIST_FILE}"],  
        input=payload, text=True)  
  
    # Reload dnsmasq  
    if force:  
        subprocess.run(  
            base_ssh + ["/etc/init.d/dnsmasq restart"])  
    else:  
        subprocess.run(  
            base_ssh + ["/etc/init.d/dnsmasq", "reload"])
```

Running the Demo

Get the system up in minutes. If you don't have an OpenWrt router connected, use the demo populate endpoint to seed sample data and explore the dashboard immediately.

01

Start the server

```
python3 server/main.py
```

Listener binds on `0.0.0.0:9999`; Flask UI starts on `:5000`.

02

Open the dashboard

Navigate to `http://localhost:5000/` in your browser. The SSE stream connects automatically.

03

Populate demo data

```
curl -X POST  
http://localhost:5000/api/demo/populate
```

Seeds sample queries and answers so you can see the UI populated without a router.

04

Block a domain

```
curl -X POST -H "Content-Type: application/json" \  
-d '{"domain":"ads.doubleclick.net"}' \  
http://localhost:5000/api/blocklist
```

Triggers an SSH sync to the router — dnsmasq reloads and the domain is sinkholed.

05

Run the router script

```
SERVER_IP=<your_server_ip> PORT=9999 \  
sh router-script.sh
```

Run on your OpenWrt device. DNS events will appear live in the dashboard within seconds.
